DISCLAIMER

- President of the World Institute of Pain

OBJECTIVES

- Review necessary equipment to perform the lysis procedure
- Overview of the procedure:
 - Caudal approach
- Identify complications

"CLASSIC" LYSIS PROTOCOL

- Needle placed with paramedian approach
- Epidurogram with 10 ml non-ionic, water-soluble contrast
- Catheter inserted ventral-lateral epidural space to target level
- Contrast 1-3 ml
- 150-300 units Hylanex in 10 ml PFNS
- Contrast 1-3 ml
- 10 ml local anesthetic/steroid
- 10 ml hypertonic saline (10%) infusion

May repeat times 2

MEDICATION

- Contrast
 - Non-ionic, water-soluble (Iohexol-240)
 - DO NOT USE ionic, non-water soluble contrast including: Hypaque®, Renagrafin/Urografen®, or Conray®
- Steroids
 - Particulate (Non-soluble) vs. non-particulate (Soluble)
- Local Anesthetic
 - 0.25% bupivacaine, 0.2% ropivacaine
- Hyaluronidase
 - Human recombinant: 150-300 units
- Hypertonic saline (10%)

MEDICATION

- Volume
 - Depends on the targeted level
 - 5-10 ml's total volume of each medication
 - Contrast
 - Local anesthetic/steroid
 - Hypertonic saline
- Usually:
 - 5-6 ml cervical
 - 8 ml thoracic
 - 10 ml caudal

HYALURONIDASE

- Mechanism of action
 - More correctly termed hyaluronoglucosaminidase
 - Liquifies the interstitial barrier between cells by cleaving β -1,4 glycosidic bonds
 - Improves the diffusion of injected substances within most connective tissue planes except for collagenous barriers.

Watson D. Hyaluronidase. *Br J Anaesth* 1993;71:422-425

HYALURONIDASE

- Mechanism of action
 - In the lysis procedure, it presumably breaks down the ground substance in the epidural scar tissue to “free up” the nerve root and to better allow deposition of local anesthetic/steroid/hypertonic saline to the target level

Hyaluronidase decreases neutrophils infiltration to the inflammatory site

Abstract

Objective To evaluate the in vivo anti-inflammatory potential of bovine hyaluronidase (HYAL) using two different models of acute inflammation.

Methods Air pouches were produced in the dorsal subcutaneous of mice and injected with phosphate saline solution or HYAL. The antiinflammatory action of HYAL was evaluated in carrageenan (Cg)-inflamed air pouches. After 4 and 24 h the cellular influx, protein exudation, cytokines and lipid mediators were evaluated. The action of HYAL on the rolling and adhesion of leukocytes was investigated in the LPS-stimulated mesenteric microcirculation by intravital microscopic.

Results Treatment with HYAL reduced the cellular influx and protein exudation in non-inflamed and inflamed air pouches. HYAL treatment of Cg-inflamed air pouch reduced the production of tumor necrosis factor-alpha

(TNF- α), interleukin-8 (IL-8), leukotriene B₄ (LTB₄) and LTC₄, whereas prostaglandins E₂ (PGE₂) and D₂ (PGD₂) concentrations were unchanged. Histological analyses showed that HYAL administration diminished cell infiltration in the air-pouch lining. In LPS-stimulated mesenteric microcirculation, HYAL usage decreased rolling and adhesion of leukocytes, but did not affect the blood vessels diameters.

Conclusion The results demonstrate that HYAL inhibited cellular recruitment, edema formation and pro-inflammatory mediators production, resulting in decreased adherence of leukocytes to blood vessels and tissue infiltration. Our data suggest that HYAL may be considered an effective candidate to ameliorate acute inflammation.

Keywords Air pouch · Cytokines · Lipid mediators · Intravital microscopy · Leukocyte–endothelial interactions · Neutrophil influx · Carrageenan · LPS

Cg = carrageenan

Fig. 5 Hyaluronidase (HYAL) affects cellular recruitment in the inflamed air-pouch lining tissue. Pouches were inoculated with Cg (1 % concentration) and 1 h later treated with HYAL (Cg + HYAL 16 U/0.5 mL/pouch) or phosphate buffered saline (PBS) (Cg + PBS/0.5 mL/pouch). Paraffin-air pouch membrane sections were stained

with hematoxylin and eosin to evaluate the inflammatory infiltrate response by image analysis. The inserts depicted from the skin-tissue linings surrounding the pouch cavity ($\times 400$ original magnification) shows the infiltrating cells. The sections were photographed at $\times 100$

HYALURONIDASE

- Currently available hyaluronidase preparations
 - Hylenex®
 - Human recombinant hyaluronidase
 - Produced by genetically engineered Chinese hamster ovary cells
 - Vitrase®
 - Ovine hyaluronidase
 - Amphidase®
 - Purified bovine testicular hyaluronidase
 - Compounded hyaluronidase formulations

CORTICOSTEROIDS

- Mechanism of action
 - Reduce inflammation either by inhibiting the synthesis or release of a number of pro-inflammatory substances or by causing a reversible local anesthetic effect
 - Others
 - Membrane stabilization
 - Inhibition of neural peptide synthesis or action
 - Blockade of phospholipase A2 activity
 - Prolonged suppression of ongoing neuronal discharge
 - Suppression of sensitization of dorsal horn neurons

Table 1. *Profile of commonly used epidural steroids*

Drug	Equivalent Dose	Epidural Dose	Anti-inflammatory Potency	Sodium Retention Capacity	Duration of Adrenal Suppression		
					IM	Single Epidural	Three Epidurals
Hydrocortisone	20 mg	N/A	1	1	N/A	N/A	N/A
Depo-Methyl Prednisolone (Depo-Medrol)	4 mg	40-80 mg	5	0.5	1-6 weeks	1-3 weeks	N/A
Triamcinolone diacetate (Aristocort)	4 mg	25-50 mg	5	0	1-2 weeks	1-5 weeks	N/A
Triamcinolone acetonide (Keralog)	4 mg	40-80 mg	5	0	2-6 weeks	N/A	2-3 months
Betamethasone (Celestone Soluspan)	0.6 mg	6-12 mg	25	0	1-2 weeks	N/A	N/A

CORTICOSTEROIDS

HYPERTONIC SALINE

- Possible mechanisms of action when injected in the epidural space for analgesia
 - Evidence from studies on cats and monkeys that hypertonic saline has a local anesthetic-like effect on intact dorsal rootlets
 - The chloride ion seems to play a major role in the persistent C-fiber blockade
 - Choline chloride just as effective as sodium chloride

Jewett D, King JS. Conduction blockade of monkey dorsal rootlets by water and hypertonic saline solutions. *Exp Neurol* 1971;33:225-237.

King JS, Jewett D, Sundberg H. Differential blockade of cat dorsal root C-fibers by various chloride solutions. *J Neurosurg* 1972;36:569-583.

HYPERTONIC SALINE

- Possible mechanisms of action when injected in the epidural space for analgesia
 - Reduction of cell swelling (edema) by causing water to migrate out of cells
 - Osmotically induced water shift
 - Decreased swelling → less pressure on nerve

COMPLICATIONS RELATED TO LYSIS OF EPIDURAL ADHESIONS

- Allergic Reactions
- Headache
- Iatrogenic Cushingoid Syndrome
- Macular Hemorrhage
- Somatosensory and Somatomotor Dysfunction
- Bowel, Bladder, Sexual dysfunction
- Infection
- Pain at epidural entry site
- Local anesthetic toxicity – CNS, cardiovascular
- Catheter shearing
- Subdural or intrathecal spread of medication

COMPLICATIONS AND PITFALLS IN LOA

COMPLICATIONS RELATED TO LYSIS OF EPIDURAL ADHESIONS

- Allergic Reactions
- Headache
- Iatrogenic Cushingoid Syndrome
- Macular Hemorrhage
- Somatosensory and Somatomotor Dysfunction
- Bowel, Bladder, Sexual dysfunction
- Infection
- Pain at epidural entry site
- Local anesthetic toxicity – CNS, cardiovascular
- Catheter shearing
- Subdural or intrathecal spread of medication

1. Needle tip can be in two spaces -

2. Injection through the Tuohy needle can be epidural and subdural at the same time.

3. Catheter finds the dural tear and enters the subdural space.

4. Catheter advanced into subdural space.

6. Subdural curcumferential spread.

7. Catheter has perforated arachnoid, leading to subarachnoid spread.
